Type Package

Title Cusp-Catastrophe Model Fitting Using Maximum Likelihood

Version 2.3.3

Imports stats, graphics, grDevices, utils

Author Raoul P. P. P. Grasman [aut, cre, cph]

Maintainer Raoul Grasman <rgrasman@uva.nl>

LazyData yes

NeedsCompilation yes

Suggests plot3D

Description Cobb's maximum likelihood method for cusp-catastrophe modeling
(Grasman, van der Maas, & Wagenmakers, 2009, JSS, 32:8;
Cobb, L, 1981, Behavioral Science, 26:1, 75--78).
Includes a cusp() function for model fitting, and several
utility functions for plotting, and for comparing the
model to linear regression and logistic curve models.

`cusp-package` *Cusp Catastrophe Modeling*

Description

Fits cusp catastrophe to data using Cobb's maximum likelihood method with a different algorithm. The package contains utility functions for plotting, and for comparing the model to linear regression and logistic curve models. The package allows for multivariate response subspace modelling in the sense of the GEMCAT software of Oliva et al.

Details

Package:	cusp
Type:	Package
Version:	2.0
Date:	2008-02-14
License:	GNU GPL v2 (or higher)

This package helps fitting Cusp catastrophy models to data, as advanced in Cobb et al. (1985). The main functions are

`cusp`	Fit Cobb's Cusp catastrophe model; see example below.
`summary.cusp`	Summary statistics of cusp model fit.
`confint.cusp`	Confidence intervals for parameter estimates
`plot.cusp`	Diagnostic plots for cusp model fit
`cusp3d`	3D graphical display of cusp model fit (experimental).
`dcusp`	Density of Cobb's cusp distribtution
`pcusp`	Cumulative probability function of Cobb's cusp distribution
`qcusp`	Quantile function of Cobb's cusp distribution

`rcusp`	Sample from Cobb's cusp distribution.
`cusp.logist`	Fit logistic model for bifurctation testing (experimental)

Author(s)

Raoul Grasman <rgrasman@uva.nl>

Examples

```
set.seed(123)
# fitting cusp to cusp data
x <- rcusp(100, alpha=0, beta=1)
fit <- cusp(y ~ x, alpha ~ 1, beta ~ 1)
print(fit)

# example with regressors
## Not run:
x1 = runif(150)
x2 = runif(150)
z = Vectorize(rcusp)(1, 4*x1-2, 4*x2-1)
data <- data.frame(x1, x2, z)
fit <- cusp(y ~ z, alpha ~ x1+x2, beta ~ x1+x2, data)
print(fit)
summary(fit)
plot(fit)
cusp3d(fit)

## End(Not run)

# use of OK
npar <- length(fit$par)
## Not run:
while(!fit$OK) # refit if necessary until convergence is OK
    fit <- cusp(y ~ z, alpha ~ x1+x2, beta ~ x1+x2, data, start=rnorm(npar))

## End(Not run)
```

```
## Not run:
# example 1 from paper
data(attitudes)
data(attitudeStartingValues)
fit.attitudes <- cusp(y ~ Attitude, alpha ~ Orient + Involv, beta ~ Involv,
 data = attitudes, start=attitudeStartingValues)

summary(fit.attitudes)
plot(fit.attitudes)
cusp3d(fit.attitudes, B = 0.75, Y = 1.35, theta = 170, phi = 30, Yfloor = -9)

## End(Not run)
```

`attitudes` *Multistability in political attitudes*

Description

Data set reflecting bistability in political attitudes

Usage

```
data(attitudes)
data(attitudeStartingValues)
```

Format

A data frame with 1387 observations on the following 3 variables.

`Orient` a numeric vector

`Involv` a numeric vector

`Attitude` a numeric vector

The format of attitudeStartingValues is: num [1:7] 0.153 -0.453 -0.097 -0.124 -0.227 ...

Details

The data set was taken from (van der Maas, Kolstein, & van der Pligt, 2003). It concerns attitudinal response transitions with respect to the statement "The government must force companies to let their workers benefit from the profit as much as the shareholders do". Responses of some 1387 Dutch respondents are included who indicated their level of agreement with this statement on a 5 point scale (1 = total ly agree, 5 = total ly disagree). As a normal factor political orientation (measures on a 10 point scale from 1 = left wing to 10 = right wing) was used. As a bifurcation factor the total score on a 12 item political involvement scale was used. The theoretical social psychological details are discussed in (van der Maas et al. 2003).

The starting values provided here for a cusp analysis of the `attitude` data set give proper convergence in one run. They were found after many trial starting values that yielded improper convergence.

Examples

```
data(attitudes)
data(attitudeStartingValues)
## Not run:
fit <- cusp(y ~ Attitude,
alpha ~ Orient + Involv,
beta ~ Involv,
data = attitudes, start=attitudeStartingValues)

## End(Not run)
## maybe str(attitudeStartingValues) ; plot(attitudeStartingValues) ...
```

---

cusp *Fit a Cusp Catatrophe Model to Data*

Description

This function fits a cusp catatrophe model to data using the maximum likelihood method of Cobb. Both the state variable may be modelled by a linear combination of variables and design factors, as well as the normal/asymmetry factor `alpha` and bifurction/splitting factor `beta`.

Usage

```
cusp(formula, alpha, beta, data, weights, offset, ..., control =
    glm.control(), method = "cusp.fit", optim.method = "L-BFGS-B", model = TRUE,
    contrasts = NULL)
```

Arguments

`formula`	`formula` that models the canonical state variable
`alpha`	`formula` that models the canonical normal/asymmetry factor
`beta`	`formula` that models the canonical bifurcation/splitting factor
`data`	`data.frame` that contains all the variables named in the formulas
`weights`	vector of weights by which each data point is weighted (experimental)
`offset`	vector of offsets for the data (experimental)
`...`	named arguments that are passed to `optim`

control	glm.control object, currently unused
method	string, currently unused
optim.method	string passed to optim to choose the optimization algorithm
model	should the model matrix be returned?
contrasts	matrix of contrasts, experimental

Details

cusp fits a cusp catastrophe model to data. Cobb's definition for the canonical form of the stochastic cusp catastrophe is the stochastic differential equation

$$dY_t = (\alpha + \beta Y_t - Y_t^3)dt + dW_t.$$

The stationary distribution of the 'behavioral', or 'state' variable Y, given the control parameters α ('asymmetry' or 'normal' factor) and β ('bifurcation' or 'splitting' factor) is

$$f(y) = \Psi \exp(\alpha y + \beta y^2/2 - y^4/4),$$

where Ψ is a normalizing constant.

The behavioral variable and the asymmetry and bifurcation factors are usually not directly related to the dependent and independent variables in the data set. These are therefore used to predict the state variable and control parameters:

$$y_i = w_0 + w_1 Y_{i1} + \cdots + w_p Y_{ip}$$

$$\alpha_i = a_0 + a_1 X_{i1} + \cdots + a_p X_{ip}$$

$$\beta_i = b_0 + b_1 X_{i1} + \cdots + b_q X_{iq}$$

in which the a_j's, b_j's, and w_j's are estimated by means of maximum likelihood. Here, the Y_{ij}'s and X_{ij}'s are variables constructed from variables in the data set. Variables predicting the α's and β's need not be the same.

The state variable and control parameters can be modelled by specifying a model formula:

```
y ~ model,

alpha ~ model,

beta ~ model,
```

in which model can be any valid formula specified in terms of variables that are present in the data.frame.

Value

List with components

coefficients	Estimated coefficients
rank	rank of Hessian matrix
qr	qr decomposition of the Hessian matrix

`linear.predictors`
: two column matrix containing the α_i's and β_i's for each case

`deviance`
: sum of squared errors using Delay convention

`aic`
: AIC

`null.deviance`
: variance of canonical state variable

`iter`
: number of optimization iterations

`weights`
: weights provided through weights argument

`df.residual`
: residual degrees of freedom

`df.null`
: degrees of freedom of constant model for state variable

`y`
: predicted values of state variable

`converged`
: convergence status given by `optim`

`par`
: parameter estimates for `qr` standardized data

`Hessian`
: Hessian matrix of negative log likelihood function at minimum

`hessian.untransformed`
: Hessian matrix of negative log likelihood for `qr` standardized data

`code`
: `optim` convergence indicator

`model`
: list with model design matrices

`call`
: function call that created the object

`formula`
: list with the formulas

`OK`
: logical. `TRUE` if Hessian matrix is positive definite at the minimum obtained

`data`
: original data.frame

`cusp-package`.

`summary.cusp` for summaries and model assessment.

The generic functions `coef`, `effects`, `residuals`, `fitted`, `vcov`.

`predict` for estimated values of the control parameters $\alpha[i]$ and $\beta[i]$,

Examples

```
set.seed(123)
# example with regressors
x1 = runif(150)
x2 = runif(150)
z = Vectorize(rcusp)(1, 4*x1-2, 4*x2-1)
data <- data.frame(x1, x2, z)
fit <- cusp(y ~ z, alpha ~ x1+x2, beta ~ x1+x2, data)
print(fit)
summary(fit)
## Not run:
plot(fit)
cusp3d(fit)

## End(Not run)

# useful use of OK
## Not run:
while(!fit$OK)
    fit <- cusp(y ~ z, alpha ~ x1+x2, beta ~ x1+x2, data,
            start=rnorm(fit$par)) # use different starting values

## End(Not run)
```

`cusp.bifset` *compute normal/symmetry factor borders of bifurcation set of cusp catastrophe*

Description

Given bifurcation/splitting factor values this function computes the border values of the normal/symmetry factor for the bifurcation set of the cusp catastrophe.

Usage

```
cusp.bifset(beta)
```

Arguments

`beta`	values of the bifurcation/splitting factor at which the border values of the normal/symmetry factor is computed

Value

Matrix with columns named `beta`, `alpha.l`, `alpha.u`. The latter two columns give respectively the lower and upper border values of the normal/symmetry factor. Negative values of `beta` give `NaN` values for the normal factor.

Examples

```
cusp.bifset(-3:3)
```

`cusp.extrema` *Locate Extrema of Cusp Catastrophe Potential Function*

Description

This function computes the locations of the extrema of the cusp catastrophe potential function.

Usage

```
cusp.extrema(alpha, beta)
```

Arguments

`alpha`	(single) value of normal/symmetry factor
`beta`	(single) value of bifurcation/splitting factor

Details

The locations are determined by computing the solutions to the equation

$$\alpha + \beta X - X^3 = 0.$$

Value

Ordered vector with locations of extremes.

Note

Use `Vectorize` to allow for array input.

Author(s)

Raoul Grasman

cusp.bifset

Examples

```
# simple use
cusp.extrema(2,3)

# using vectorize to allow for array input;
# returns a matrix with locations in each column
Vectorize(cusp.extrema)(-3:3, 2)
```

---

cusp.logist *Fit a Logistic Surface Model to Data*

Description

This function fits a logistic curve model to data using maximum likelihood under the assumption of normal errors (i.e., nonlinear least squares). Both the response variable may be modelled by a linear combination of variables and design factors, as well as the normal/asymmetry factor `alpha` and bifurction/splitting factor `beta`.

Usage

```
cusp.logist(formula, alpha, beta, data, ..., model = TRUE, x =
                FALSE, y = TRUE)
```

Arguments

`formula, alpha, beta`	formulas for the response variable and the regression variables (see below)
`data`	data.frame containing n observations of all the variables named in the formulas
`...`	named arguments that are passed to nlm
`model, x, y`	logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, and the response are returned.

Details

A nonlinear regression is carried out of the model

$$y_i = \frac{1}{1 + \exp(-\alpha_i/\beta_i^2)} + \epsilon_i$$

for $i = 1, 2, \ldots, n$, where

$$y_i = w_0 + w_1 Y_{i1} + \cdots + w_p Y_{ip}$$

$$\alpha_i = a_0 + a_1 X_{i1} + \cdots + a_p X_{ip}$$

$$\beta_i = b_0 + b_1 X_{i1} + \cdots + b_q X_{iq}$$

in which the a_j's, and b_j's, are estimated. The Y_{ij}'s are variables in the data set and specified by `formula`; the X_{ij}'s are variables in the data set and are specified in `alpha` and `beta`. Variables in `alpha` and `beta` need not be the same. The w_j's are estimated implicitely using concentrated likelihood methods, and are not returned explicitely.

Value

List with components

`minimum`	Objective function value at minimum
`estimate`	Coordinates of objective function minimum
`gradient`	Gradient of objective function at minimum.
`code`	Convergence code returned by `optim`
`iterations`	Number of iterations used by `optim`
`coefficients`	A named vector of estimates of a_j, b_j's
`linear.predictors`	Estimates of α_i's and β_i's.
`fitted.values`	Predicted values of y_i's as determined from the `linear.predictors`
`residuals`	Residuals
`rank`	Numerical rank of matrix of predictors for α_i's plus rank of matrix of predictors for β_i's plus rank of matrix of predictors for the y_i's.
`deviance`	Residual sum of squares.
`logLik`	Log of the likelihood at the minimum.
`aic`	Akaike's information criterion
`rsq`	R Squared (proportion of explained variance)
`df.residual`	Degrees of freedom for the residual
`df.null`	Degrees of freedom for the Null residual
`rss`	Residual sum of squares
`hessian`	Hessian matrix of objective function at the minimum if `hessian=TRUE`.
`Hessian`	Hessian matrix of log-likelihood function at the minimum (currently unavailable)
`qr`	QR decomposition of the `hessian` matrix
`converged`	Boolean indicating if optimization convergence is proper (based on exit code `optim`, gradient, and, if `hessian=TRUE` eigen values of the hessian).
`weights`	`weights` (currently unused)
`call`	the matched call
`y`	If requested (the default), the matrix of response variables used.
`x`	If requested, the model matrix used.
`null.deviance`	The sum of squared deviations from the mean of the estimated y_i's.

cusp.nc *Calculate the Normalizing Constant of Cobb's Cusp Density*

Description

A family of functions that return the normalization constant for the cusp density given the values of the bifurcation and asymmetry parameters (default), or returns the moment of a specified order (cusp.nc).

Usage

```
cusp.nc(alpha, beta, mom.order = 0, ...)
cusp.nc.c(alpha, beta, ..., keep.order = TRUE)
cusp.nc.C(alpha, beta, subdivisions = 100, rel.tol = .Machine$double.eps^0.25,
    abs.tol = rel.tol, stop.on.error = TRUE, aux = NULL, keep.order = TRUE)
cusp.nc.vec(alpha, beta, ..., keep.order = FALSE)
```

Arguments

alpha	the asymmetry parameter in Cobb's cusp density (see cusp)
beta	the bifurcation parameter in Cobb's cusp density (see cusp)
mom.order	the moment order to be computed (see details below)
subdivisions, rel.tol, abs.tol, stop.on.error, aux	arguments used by the internal integration routine of R (see integrate)
keep.order	logical, that indicates wether the order of the output should be the same as the order of the input
...	extra arguments in cusp.nc.c that are passed to cusp.nc.C

Details

The function cusp.nc returns Ψ if mom.order = 0 and Ψ times the moment of order mom.order otherwise.

The function cusp.nc is internally used if the C-routine symbol "cuspnc" is not loaded. The functions cusp.nc.c and cusp.nc.C call this C routine, which is considerably faster than cusp.nc.

These functions are not intended to be called directly by the user.

Value

cusp.nc, cusp.nc.c, cusp.nc.vec return a numeric vector of the same length as alpha and beta with normalizing constants, or the indicated moments times the normalization constant (cusp.nc only).

cusp.nc.C returns a list with vectors with the results obtained from integrate. cusp.nc.c first sorts the input in such a way that the numerical integrals can be evaluated more quickly than in arbitrary order

```

---

cusp.nlogLike *Negative log-likelihood for Cobb's cusp density*

Description

(Negative) log-likelihood for Cobb's cusp probability density function used by cusp. This function is not to be called by the user. See help(cusp).

Usage

```
cusp.nlogLike(p, y, X.alpha, X.beta = X.alpha, ..., verbose = FALSE)
cusp.nlogLike.c(p, y, X.alpha, X.beta = X.alpha, ..., verbose = FALSE)
cusp.logLike(p, x, verbose = FALSE)
```

Arguments

p	parameter vector
x	vector of observed values for the state variable in the cusp (cusp.nlogLike only)
y	design matrix predicting state values at which the likelihood is evaluated
X.alpha	design matrix predicting alpha in the model
X.beta	design matrix predicting beta in the model
...	unused extra arguments
verbose	logical, if TRUE the value of the parameters are printed to the console

Details

cusp.nlogLike is the R version of the corresponding C function wrapped by cusp.nlogLike.c

These functions are not intended to be called directly by the user.

Value

The value of the negative log-likelihood function (cusp.nlogLike, cusp.nlogLike.c), the value of the log-likelihood function (cusp.logLike).

Note

The functions are not to be called by the user directly.

Author(s)

Raoul Grasman

```

cusp3d *Generate 3D plot of Cusp Catatrophe Model Fit*

Description

This function generates a 3D display of the fit (object) of a cusp model.

Usage

```
cusp3d(y, alpha = if (!missing(y) && is.list(y)) y$lin[, "alpha"],
    beta = if (!missing(y) && is.list(y)) y$lin[, "beta"], w = 0.03,
    theta = 170, phi = 35, B = 4, Y = 3, Yfloor = -15,
    np = 180, n.surface = 30, surface.plot = TRUE,
    surf.alpha = 0.75, surf.gamma = 1.5, surf.chroma = 35, surf.hue = 240,
    surf.ltheta = 0, surf.lphi = 45, ...)
```

Arguments

y	object returned by cusp or a vector of observed state values
alpha	vector of normal/symmetry factor values corresponding to the state values in y
beta	vector of bifurcation/splitting factor values corresponding to the state values in y
w	number that specifies the size of the data points plotted on the cusp surface
theta, phi	angles defining the viewing direction. theta gives the azimuthal direction and phi the colatitude.
B	range of the splitting factor axis
Y	range of the state variable axis
Yfloor	location on state variable axis where the control surface is plotted
np	factor that determines the fineness of the drawing
n.surface	factor that determines the fineness of the rendered surface
surface.plot	plot the surface?
surf.alpha	transparency level of rendered surface
surf.gamma	factor that determines the shading of surface facets (surf.gamma<1 deminishes shading, surf.gamma>1 exagerates shading)
surf.chroma, surf.hue	chroma and hue of surface color (see hcl)
surf.ltheta, surf.lphi	the surface is shaded as though it was being illuminated from the direction specified by azimuth surf.ltheta and colatitude surf.lphi
...	named parameters that are pased to persp

Details

This function is experimental.

Value

cusp3d returns the viewing transformation matrix, say VT, a 4 x 4 matrix suitable for projecting 3D coordinates (x,y,z) into the 2D plane using homogeneous 4D coordinates (x,y,z,t). It can be used to superimpose additional graphical elements on the 3D plot, by lines() or points(), using the simple function trans3d().

Note

Currently still somewhat buggy.

```
set.seed(123)
x1 = runif(150)
x2 = runif(150)
z = Vectorize(rcusp)(1, 4*x1-2, 4*x2-1)
data <- data.frame(x1, x2, z)
fit <- cusp(y ~ z, alpha ~ x1+x2, beta ~ x1+x2, data)
## Not run:
cusp3d(fit)

## End(Not run)
```

---

cusp3d.surface *Generate 3D plot of the Cusp surface*

Description

This function generates a 3D display of the cusp equilibrium surface.

Usage

```
cusp3d.surface(alpha = c(-5, 5), beta = c(-3, 3), y = 41,
xlim = range(alpha), ylim = range(beta), zlim = c(-5, 4),
xlab = expression(alpha), ylab = expression(beta), zlab = "equilibrium states",
main = NULL, sub = NULL, phi = 20, theta = 160,
r = sqrt(3), d = 1, scale = TRUE, expand = 1, hue = 240,
chroma = 35, surf.alpha = 0.75, gamma = 1.5, bcol = NA,
lcol = "gray", ltheta = 90, lphi = 70, box = TRUE,
axes = FALSE, nticks = 5, ticktype = "simple", floor.lines = TRUE, ...)
```

Arguments

alpha	numeric 2-vector specifying the normal/symmetry factor axis range
beta	numeric 2-vector specifying the bifurcation/splitting factor axis range
y	numeric specifying the iso contours used to render the surface (see detais below)
xlim,ylim,zlim	numeric 2-vectors (see persp)
xlab,ylab,zlab,main,sub	strings (see persp)
phi,theta	numeric, determine viewing direction (see persp)
r	numeric, distance to center of the plotting box (see persp)
d	numeric, strength of perspective transformation (see persp)
scale,expand	logical, see persp
hue,chroma,surf.alpha	hue, chroma and alpha (transparency) of the surface segments (see hcl)
gamma	gamma for shading of surface (see cusp3d)
bcol	color, NA, or string "surface". Color of the border of each surface element; NA gives transparent borders; "surface" tries to hide the border as much as possible by giving it the same color as the surface segment.
lcol	color of the lines on the floor of the plotting cube
ltheta,lphi	numeric, direction of illumination of the surface (similar to persp)
box,axes,nticks,ticktype	(see persp)
floor.lines	logical, if TRUE (default) iso-contours are projected on the floor of the plotting cube (revealing the bifurcation set)
...	extra arguments that are passed to lines and polygon

Details

If y has length 1, it is interpreted as the number of contours. Otherwise it is interpreted as a vector of contour levels from which the surface must be determined. If y is a number, the exact range of y is determined by the ranges of alpha and beta through the cusp equilibrium equation below.

The surface is constructed from the iso-contours of the cusp equilibrium surface that makes up the solutions to

$$\alpha + \beta * y - y^3 = 0$$

as a (multi-)function of the asymmetry variable α and bifurcation variable β. For each possible solution y the iso-contours are given by the equation

$$\alpha = (\beta * y - y^3)/y,$$

which are linear in β. For each value of y the values of $alpha$ are determined for the end points of the $beta$ range specified by `beta`. The two 3D coordinates (α, β, y) are projected onto the 2D canvas using the `persp` transformation matrix and used for drawing the lines and polygons.

Value

`cusp3d.surface` returns the viewing transformation matrix, say `VT`, a 4 x 4 matrix suitable for projecting 3D coordinates (x,y,z) into the 2D plane using homogeneous 4D coordinates (x,y,z,t). It can be used to superimpose additional graphical elements on the 3D plot, by lines() or points(), using the simple function trans3d().

Note

This function is an alternative to `cusp3d` which uses a different method of rendering and also plots fitted points on the surface.

## End(Not run)
```

dcusp *Cobb's Cusp Distribution*

Description

Functions for the cusp distribution.

Usage

```
dcusp(y, alpha, beta)
pcusp(y, alpha, beta, subdivisions = 100, rel.tol = .Machine$double.eps^0.25,
          abs.tol = rel.tol, stop.on.error = TRUE, aux = NULL, keep.order = TRUE)
qcusp(p, alpha, beta)
rcusp(n, alpha, beta)
```

Arguments

y	vector of quantiles
p	vector of probabilities
n	number of observations.
alpha	normal/asymmetry factor value of cusp density
beta	bifurcation/splitting factor value of cusp density
subdivisions	See cusp-package.
rel.tol	See cusp-package.
abs.tol	See cusp-package.
stop.on.error	See cusp-package.
aux	See cusp-package.
keep.order	logical. If true the order of the output values is the same as those of the input values y

Details

The cusp distribution is defined by

$$f(y) = \Psi \exp(\alpha y + \beta y^2/2 - y^4/4),$$

where Ψ is the normalizing constant.

rcusp uses rejection sampling to generate samples.

qcusp implements binary search and is rather slow.

Value

dcusp gives the density function, pcusp gives the distribution function, qcusp gives the quantile function, and rcusp generates observations.

draw.cusp.bifset *Add Cusp Bifurcation Set Diagram to Existing Plot*

Description

Add a miniature bifurcation set for the cusp catastrophe to an existing plot.

Usage

```
draw.cusp.bifset(rx = par("usr")[1:2], ry = par("usr")[3:4], xpos = min(rx) +
    0.01 * diff(rx)[1], ypos = max(ry) - 0.01 * diff(ry)[1],
    xscale =  0.1 * diff(rx), yscale =  0.1 * diff(ry) / xscale,
    aspect = 1, mark = 1, col = hsv(0.7, s = 0.8, alpha = 0.5),
    border = NA, density = NA, bifurcation.set.fill = gray(0.8),
    background = hsv(0.1, s = 0.1, alpha = 0.5), ..., X)
```

Arguments

rx	x-axis range of the plot window
ry	y-axis range of the plot window
xpos	x-axis position of drawing

ypos	y-axis position of drawing
xscale	scaling applied to drawing along x-axis
yscale	scaling applied to drawing along y-axis
aspect	aspect ratio
mark	0, 1, 2, 3, or 4; indicates which part of the cusp surface should be marked
col	color used for marking a part of the cusp surface
border	color used for the marked part of the cusp surface. See polygon for details.
density	the density of shading lines of the marked part of the cusp surface, in lines per inch. The default value of NULL means that no shading lines are drawn. See polygon for details.
bifurcation.set.fill	color for marking the bifurcation set
background	background color of the cusp surface
...	arguments passed to rect and polygon
X	data.frame, depricated

Details

This function is mainly intended for internal use by cusp.plot.

`oliva` *Synthetic cusp data set*

Description

Synthetic 'multivariate' data from the cusp catastrophe as generated from the equations specified by Oliva et al. (1987).

Usage

```
data(oliva)
```

Format

A data frame with 50 observations on the following 12 variables.

`x1` splitting factor predictor

`x2` splitting factor predictor

`x3` splitting factor predictor

`y1` the bifurcation factor predictor

`y2` the bifurcation factor predictor

`y3` the bifurcation factor predictor

`y4` the bifurcation factor predictor

`z1` the state factor predictor

`z2` the state factor predictor

`alpha` the true $alpha$'s

`beta` the true $beta$'s

`y` the true state variable values

Details

The data in Oliva et al. (1987) are obtained from the equations

$$\alpha_i = X_{i1} - .969\, X_{i2} - .201\, X_{i3},$$

$$\beta_i = .44\, Y_{i1} + 0.08\, Y_{i2} + .67\, Y_{i3} + .19\, Y_{i4},$$

$$y_i = -0.52\, Z_{i1} - 1.60\, Z_{i2}.$$

Here the X_{ij}'s are uniformly distributed on (-2,2), and the Y_{ij}'s and Z_{i1} are uniform on (-3,3). The states y_i were then generated from the cusp density, using `rcusp`, with their respective α_i's and β_i's as normal and splitting factors, and then Z_2 was computed as

$$Z_{i2} = (y_i + 0.52 Z_{i1})/(1.60).$$

Examples

```
data(oliva)
set.seed(121)
fit <- cusp(y ~ z1 + z2 - 1,
alpha ~ x1 + x2 + x3 - 1, ~ y1 + y2 + y3 + y4 - 1,
data = oliva, start = rnorm(9))
summary(fit)
## Not run:
cusp3d(fit, B=5.25, n.surf=50, theta=150)
# B modifies the range of beta (is set here to 5.25 to make
# sure all points lie on the surface)

## End(Not run)
```

---

plot.cusp *Graphical Diagnostic Display of Cusp Catastrophe Data Fit*

Description

This function generates diagnostic graphical displays of fits of a cusp catastrophe model to data obtained with cusp

Usage

```
## S3 method for class 'cusp'
plot(x, what = c("all", "bifurcation", "residual", "densities"), ...)
```

Arguments

x	Object returned by cusp
what	1-character string giving the type of plot desired. The following values are possible: "all" for a panel plot with all diagnostic plots, "bifurcation" for a plot of the bifurcation surface with estimated control parameter locations superimposed, "residual" for a plot of the residuals against fitted values, "densities" for a plot of density estimates conditioned on the estimated location on the bifurcation surface.
...	named arguments that are passed to lower level plotting function

plotCuspBifurcation *Display Fitted Data on Control Plane of Cusp Catastrophe.*

Description

Displays fitted data points on the control plane of cusp catastrophe. The function takes a fit object obtained with cusp and generates a plot. Different diagnostic plots may be chosen, or all can be combined in a single plot (the default).

Usage

```
plotCuspBifurcation(object, xlim = a + c(-0.3, 0.3), ylim = b + c(-0.1,
                0.1), xlab = expression(alpha), ylab =
                expression(beta), hue = 0.5 + 0.25 * tanh(object$y),
                col = hsv(h = hue, s = 1, alpha = 0.4), cex.xlab =
                1.55, cex.ylab = cex.xlab, axes = TRUE, box = TRUE,
                add = FALSE, bifurcation.set.fill = gray(0.8),
                cex.scale = 15, cex = (cex.scale/log(NROW(ab))) *
                dens/max(dens), pch = 20)
```

Arguments

object	object returned by cusp
xlim	the x limits (x1, x2) of the plot.
ylim	the y limits of the plot.
xlab	a label for the x axis.
ylab	a label for the x axis.
hue	hue of points (see hsv)
col	color used in plots
cex.xlab, cex.ylab	see par
axes	logical. Should the axes be displayed?
box	logical. Should a box be drawn around the plot?
add	logical. Add to current plot?
bifurcation.set.fill	1-character string. Color used to fill the bifurcation set (see colors).
cex.scale, cex, pch	see par

Details

The default hue of each dot is a function of the height of the cusp surface to which it is closest. This is especially usefull in the bifurcation set. Purple dots are higher than green dots.

The size of the dots depends on the density of dots at its location. The higher the density the larger the dot.

`plotCuspDensities` *Plot Cusp State Variable Densities Conditioned on Control Parameter Values*

Description

Plot density of state variables conditioned on their location on the cusp control surface.

Usage

```
plotCuspDensities(object, main = "Conditional density", ...)
```

Arguments

`object`	cusp fit object returned by `cusp`
`main`	title of plot
`...`	named arguments that are passed to `plot` and `draw.cusp.bifset`

Details

This function is mainly intended for internal use by `plot.cusp`.

plotCuspResidfitted *Residuals against Fitted Plot for Cusp Model Fit*

Description

Plot Residuals against Fitted Values for a Cusp Model Fit.

Usage

```
plotCuspResidfitted(object, caption = "Residual vs Fitted",
   xlab = paste("Fitted (", colnames(fitted(object))[1], " convention)", sep = ""),
    ylab = "Residual", ...)
```

Arguments

object	cusp fit object returned by cusp
caption	plot caption
xlab	label for x-axis
ylab	label for y-axis
...	named arguments that are passed to plot

Details

This function is mainly intended for internal use by plot.cusp.

predict.cusp *Predict method for Cusp Model Fits*

Description

Predicted values based on a cusp model object.

Usage

```
## S3 method for class 'cusp'
predict(object, newdata, se.fit = FALSE, interval =
  c("none", "confidence", "prediction"), level = 0.95, type = c("response", "terms"),
   terms = NULL, na.action = na.pass, pred.var = res.var/weights, weights = 1,
  method = c("delay", "maxwell", "expected"), keep.linear.predictors = FALSE, ...)
```

Arguments

object	Object of class "cusp"
newdata	An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
se.fit	See predict.lm. Not yet used.
interval	See predict.lm. Not yet used.
level	See predict.lm. Not yet used.
type	See predict.lm. Not yet used.
terms	See predict.lm. Not yet used.
na.action	See predict.lm. Not yet used.
pred.var	See predict.lm. Not yet used.
weights	See predict.lm. Not yet used.
method	Type of prediction convention to use. Can be abbreviated. (expected should currently not be trusted).
keep.linear.predictors	Logical. Should the linear predictors (alpha, beta, and y) be returned?
...	further arguments passed to or from other methods.

Details

predict.cusp produces predicted values, obtained by evaluating the regression functions from the cusp object in the frame newdata using predict.lm. This results in linear predictors for the cusp control variables alpha, and beta, and, if method = "delay", for the behavioral cusp variable y. These are then used to compute predicted values: If method = "delay" these are the points $y*$ on the cusp surface defined by

$$V'(y*) = \alpha + \beta y * -y*^3 = 0$$

that are closest to y. If method = "maxwell" they are the points on the cusp surface corresponding to the minimum of the associated potential function $V(y*) = \alpha y * +0.5y *^2 -0.25y*^4$.

Value

A vector of predictions. If keep.linear.predictors the return value has a "data" attribute which links to newdata augmented with the linear predictors alpha, beta, and, if method = "delay", y. If method = "expected", the expected value from the equilibrium distribution of the stochastic process

$$dY_t = V'(Y_t; \alpha, \beta)dt + dW_t,$$

where W_t is a Wiener proces (aka Brownian motion) is returned. (This distribution is implemented in dcusp.)

Note

Currently method = "expected" should not be trusted.

Author(s)

Raoul Grasman

References

See cusp-package.

cusp-package, predict.lm.

Examples

```
set.seed(123)
# example with regressors
x1 = runif(150)
x2 = runif(150)
z = Vectorize(rcusp)(1, 4*x1-2, 4*x2-1)
data <- data.frame(x1, x2, z)
fit <- cusp(y ~ z, alpha ~ x1+x2, beta ~ x1+x2, data)

newdata = data.frame(x1 = runif(10), x2 = runif(10), z = 0)
predict(fit, newdata)
```

---

summary.cusp *Summarizing Cusp Catastrophe Model Fits*

Description

summary method for class "cusp"

Usage

```
## S3 method for class 'cusp'
summary(object, correlation = FALSE, symbolic.cor = FALSE, logist = FALSE, ...)

## S3 method for class 'summary.cusp'
print(x, digits = max(3, getOption("digits") - 3), symbolic.cor = x$symbolic.cor,
    signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

object	Object returned by cusp
x	'summary.cusp' object
correlation	logical; if TRUE the correlation matrix is returned
symbolic.cor	logical; currently unused

logist	logical. If TRUE a logistic model is fitted for cusp model assesment (see cusp.logist for details).
digits	numeric; the number of significant digits to use when printing.
signif.stars	logical. If TRUE, significance stars are printed for each coefficient.
...	further arguments passed to or from other methods.

Details

print.summary.cusp tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives significance stars if signif.stars is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

Value

The function summary.cusp computes and returns a list of summary statistics of the fitted linear model given in object, using the components (list elements) "call" and "terms" from its argument, plus

call	the matched call
terms	the terms object used.
deviance	sum of squared residuals of cusp model fit
aic	Akaike Information Criterion for cusp model fit
contrasts	contrasts used
df.residual	degrees of freedom for the residuals of the cusp model fit
null.deviance	variance of canonical state variable
df.null	degrees of freedom of constant model for state variable
iter	number of optimization iterations
deviance.resid	residuals computed by residuals.glm using type="deviance"
coefficients	a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.
aliased	named logical vector showing if the original coefficients are aliased.
dispersion	always 1
df	3-vector containing the rank of the model matrix, residual degrees of freedom, and model degrees of freedom.
resid.name	string specifying the convention used in determining the residuals (i.e., "Delay" or "Maxwell").
cov.unscaled	the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.

`r2lin.r.squared`
: R^2, the 'fraction of variance explained' by the linear regression model

$$w_0 + w_1 Y_{i1} + \cdots + w_p Y_{ip} = \beta_0 + \beta_1 X_{i1} + \cdots + \beta_q X_{iq} + \epsilon_i,$$

where Y containes all explanatory variables for the behavioral states in the cusp model, and X containes all explanatory variables for the control parameters of the cusp model. This is computed from the largest canonical correlation.

`r2lin.dev`
: residual sums of squares of the linear model

`r2lin.df`
: degrees of freedom for the linear model

`r2lin.logLik`
: value of the log-likelihood for the linear model assuming normal errors

`r2lin.npar`
: number of parameters in the linear model

`r2lin.aic`
: AIC for the linear model

`r2lin.aicc`
: corrected AIC for the linear model

`r2lin.bic`
: BIC for the linear model

`r2log.r.squared`
: R^2, the 'fraction of variance explained' by the logistic model. See `cusp.logist` for details.

`r2log.dev`
: if `logist = TRUE` residual sums of square for the logistic model

`r2log.df`
: ditto, degrees of freedom for the logistic model

`r2log.logLik`
: ditto, value of log-likelihood function for the logistic model assuming normal errors.

`r2log.npar`
: ditto, number of parameters for the logistic model

`r2log.aic`
: ditto, AIC for logistic model

`r2log.aicc`
: ditto, corrected AIC for logistic model

`r2log.bic`
: ditto, BIC for logistic model

`r2cusp.r.squared`
: pseudo-R^2, the 'fraction of variance explained by the cusp model',

$$R^2 = 1 - \frac{Var(residuals_i)}{Var(y_i)}.$$

This value can be negative.

`r2cusp.dev`
: residual sums of squares for cusp model

`r2cusp.df`
: residual degrees of freedom for cusp model

`r2cusp.logLik`
: value of the log-likelihood function for the cusp model

`r2cusp.npar`
: number of parameters in the cusp model

`r2cusp.aic`
: AIC for cusp model fit

`r2cusp.aicc`
: corrected AIC for cusp model fit

`r2cusp.bic`
: BIC for cusp model fit.

vcov.cusp *Calculate Variance-Covariance Matrix for a Fitted Cusp Model Object*

Description

Returns an estimate of the variance-covariance matrix of the main parameters of a fitted cusp model object.

Usage

```
## S3 method for class 'cusp'
vcov(object, ...)
## S3 method for class 'cusp'
confint(object, parm, level = 0.95, ...)
```

Arguments

object	a fitted cusp model object.
parm	a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
level	the confidence level required.
...	additional arguments for method functions.

Details

The variance-covariance matrix is estimated by the inverse of the Hessian matrix of the log-likelihood at the maximum likelihood estimate (vcov).

Normal theory confidence intervals are computed for all parameters in the cusp model object using vcov to obtain the standard errors (confint).

Value

The variance-covariance matrix (vcov).

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in

zeeman *Measurements from Zeeman's Catastrophe Machine*

Description

Data sets with measurements from different physical instances of Zeeman's Catastrophe Machine

Usage

```
data(zeeman1)
data(zeeman2)
data(zeeman3)
```

Format

A data frame with 150/198/282 observations on the following 3 variables.

- x a control plane variable that are manipulable by the experimentalist
- y a control plane variable that are manipulable by the experimentalist
- z the state variable of the machine: the shortest distance to the longitudinal axis of the machine

Details

The behavior Zeeman's catastrophe machine is archetypal for the Cusp catastrophe. This device consists of a wheel is tethered by an elastic chord to a fixed point. Another elastic, also attached to the wheel is moved about in the 'control plane' area opposite to the fixed point. The shortest distance between the strap point on the wheel and the axis defined by the fixed point and the control plane is recorded as a function of the position in the control plane. (In the original machine the angle between this axis and the line through the wheel center and the strap point is used.) See http://www.math.sunysb.edu/~tony/whatsnew/column/catastrophe-0600/cusp4.html for a vivid demonstration. These data sets were obtained from 3 different physical instances of this machine, made by different people.

Measurements were made by systematically sampling different points in the control plane.

See vignette for example analysis with all three data sets.

For pictures of the machines, see
